Testing, part 2

Mutation testing

How do you
count the
Eggs in the
Zürichsee?

Mutation testing

Purpose: estimate quality of a test suite

Principle: make small changes to the program source code (so that the modified versions still compile) and see if successful test cases still succeed

If they do, the test suite is not good enough!

Terminology

Mutant: a modified version of the program, obtained by injecting a fault

- We only consider mutants that are not equivalent to the original program

Killed mutant: At least one test case detects the injected fault

Alive mutant: no test case detects the injected fault

Mutation score : measurement of effectiveness of test, defined next

Mutation operators

Mutation operator: a rule that specifies a syntactic variation of the program text so that the modified program still compiles

A mutant is the result of an application of a mutation operator

The quality of the mutation operators determines the quality of the mutation testing process

Mutation operator coverage (MOC): For each mutation operator o , there is at least one mutant using o

Examples of mutants

Original program:

```
if (a < b)
    b := b - a;
else
    b := 0;
```

Mutants:

```
if (a < b)
    if (a <= b)
        if (a > b)
            if (c < b)
                b := b - a;
                b := b + a;
                b := x - a;
            else
                b := 0;
                b := 1;
                a := 0;
```

OO mutation operators

Polymorphism- and dynamic binding-related:

➤ **Change creation type**

`create x.make` → `create {T} x.make`

➤ **Redefinition**

Replace inherited routine or attribute
by redefined version

Various:

➤ **Argument order change**

If types match, e.g. `f (x, y: INTEGER)`

➤ **Replace assignment by copy**

`list1 := list2.twin` → `list1 := list2`

System test quality (STQ)

S : system composed of n components, denoted C_i

d_i : number of killed mutants after applying test sequence to C_i

m_i : total number of mutants

Mutation score for C_i and test sequence T_i : $MS(C_i, T_i) = d_i / m_i$

System test quality:

$$STQ(S) = \frac{\sum_{i=1,n} d_i}{\sum_{i=1,n} m_i}$$

STQ provides a measure of test suite quality

If contracts are used as oracles, **STQ** is a combined measure of test and contract quality

Mutation tools

muJava - <http://ise.gmu.edu/~ofut/mujava/>

Test Coverage

Coverage

How extensive is a test?

Coverage measures a percentage of elements of a certain kind exercised by a test suite.

“Achieving coverage” means reaching 100% for the chosen criterion

Purposes of measuring code coverage

Code coverage analysis makes it possible to:

- Find sections of code not exercised by test cases
- Create additional test cases that exercise properties not previously tested
- Obtained a (hoped for) estimate of test suite quality

Code coverage analyzer

A code coverage analyzer is a tool that automatically computes the coverage achieved by a test suite

Steps involved:

1. Instrument source code by inserting trace instructions that write to a trace file
2. Run tests
3. Parse trace file to produce a coverage report

Standard measures of coverage

Instruction coverage, branch coverage etc.

Instruction (statement) coverage

Percentage of instructions (executable statements) executed

- Disadvantage: insensitive to control structures

Branch (or “decision”) coverage

Percentage of conditionals whose boolean expression has evaluated to both true and false

- Disadvantage: insensitive to individual components of boolean expression
- The most commonly used in practice (easy to achieve)

Condition coverage

Percentage of elementary boolean conditions that have evaluated to both true and false

➤ Disadvantage: Not all combinations

Example:

if **a and b** then ...

Multiple-condition coverage

Percentage of combinations of true and false values of elementary boolean conditions

- Disadvantage: difficult to achieve, widely different number of tests for similar expressions

Examples*

a and b and (c or (d and e))

1.	F	-	-	-	-
2.	T	F	-	-	-
3.	T	T	F	F	-
4.	T	T	F	T	F
5.	T	T	F	T	T
6.	T	T	T	-	-

((a or b) and (c or d)) and e

1.	F	F	-	-	-
2.	F	T	F	F	-
3.	F	T	F	T	F
4.	F	T	F	T	T
5.	F	T	T	-	F
6.	F	T	T	-	T
7.	T	-	F	F	-
8.	T	-	F	T	F
9.	T	-	F	T	T
10.	T	-	T	-	F
11.	T	-	T	-	T

*From Steve Cornett

Modified Condition/Decision coverage (MC/DC)

Percentage of combinations of elementary conditions that have evaluated to both true and false value for one of the conditions, with all the other conditions unchanged, leading to both true and false for the overall expression (decision)

Example:

(a or b) and (c or not d)

- Advantage: easier to achieve than multiple condition
- The standard at Boeing

Generalization: predicate coverage

A predicate is **covered** if at least one test run makes it true and at least one makes it false

Example:

$$a \vee b \vee (f(x) \wedge x > 0)$$

is covered by the following two test cases:

- {a=true; b=false; f(x)=false; x=1}
- {a=false; b=false; f(x)=true; x=-1}

Clause coverage (CC)

Satisfied if for every clause of the predicate at least one test run makes the clause true and at least one to false

Example:

$$x > 0 \vee y < 0$$

Clause coverage is achieved by:

- $\{x=-1; y=-1\}$
- $\{x=1; y=1\}$

Does clause coverage imply predicate coverage?

No: consider following variant:

- $\{x=-1; y=2\}$
- $\{x=1; y=1\}$

Combinatorial coverage (CoC)

The test runs must include all possible combination of clause values

Example:

$$((A \vee B) \wedge C)$$

	A	B	C	$((A \vee B) \wedge C)$
1	T	T	T	T
2	T	T	F	F
3	T	F	T	T
4	T	F	F	F
5	F	T	T	T
6	F	T	F	F
7	F	F	T	F
8	F	F	F	F

Determination

A clause c_M (called **major** clause) of a predicate p **determines** p if the remaining clauses $c_m \in p, m \neq M$ (called **minor** clauses) have such values that changing the value of c_M changes the value of p . c_M will be the **active** clause.

Example:

$$p = a \vee b$$

	a	b
$c_M = a$	T F	f f
$c_M = b$	f f	T F

Correlated Active Clause Coverage (CACCC)*

For each $p \in P$ and each major clause $c_M \in C_p$, choose minor clauses c_m , $m \neq M$ so that c_M determines p

The test runs must include at least one that makes c_M true and one that makes it false

The values chosen for the minor clauses do not need to be the same for these two runs

Example:

$$p = a \wedge (b \vee c)$$

We satisfy CACCC for a if we choose one test case out of rows 1, 2, or 3, and one out of rows 5, 6, or 7.

	a	b	c	$a \wedge (b \vee c)$
1	T	T	T	T
2	T	T	F	T
3	T	F	T	T
5	F	T	T	F
6	F	T	F	F
7	F	F	T	F

***Variant of "MCDC"**

Restricted Active Clause Coverage (RACC)

For each $p \in P$ and each major clause $c_M \in C_p$, choose minor clauses c_m , $m \neq M$ so that c_M determines p .

The test runs must include one that makes c_M true and one that makes it false

The values chosen for the minor clauses must be the same for these two runs

Example:

$$p = a \wedge (b \vee c)$$

We satisfy RACC for a if we choose (1,5), or (2,6), or (3,7).

	a	b	c	$a \wedge (b \vee c)$
1	T	T	T	T
5	F	T	T	F
2	T	T	F	T
6	F	T	F	F
3	T	F	T	T
7	F	F	T	F

Path coverage

Percentage of paths taken

A path is a unique sequence of branches from routine entry to exit

- Disadvantage: exponential
- Does not take loops into account

Can be impossible to achieve 100%

```
if c then a end  
other_instructions  
if c then b end
```

(if `other_instructions` do not affect `c`.)

Limits of coverage measures

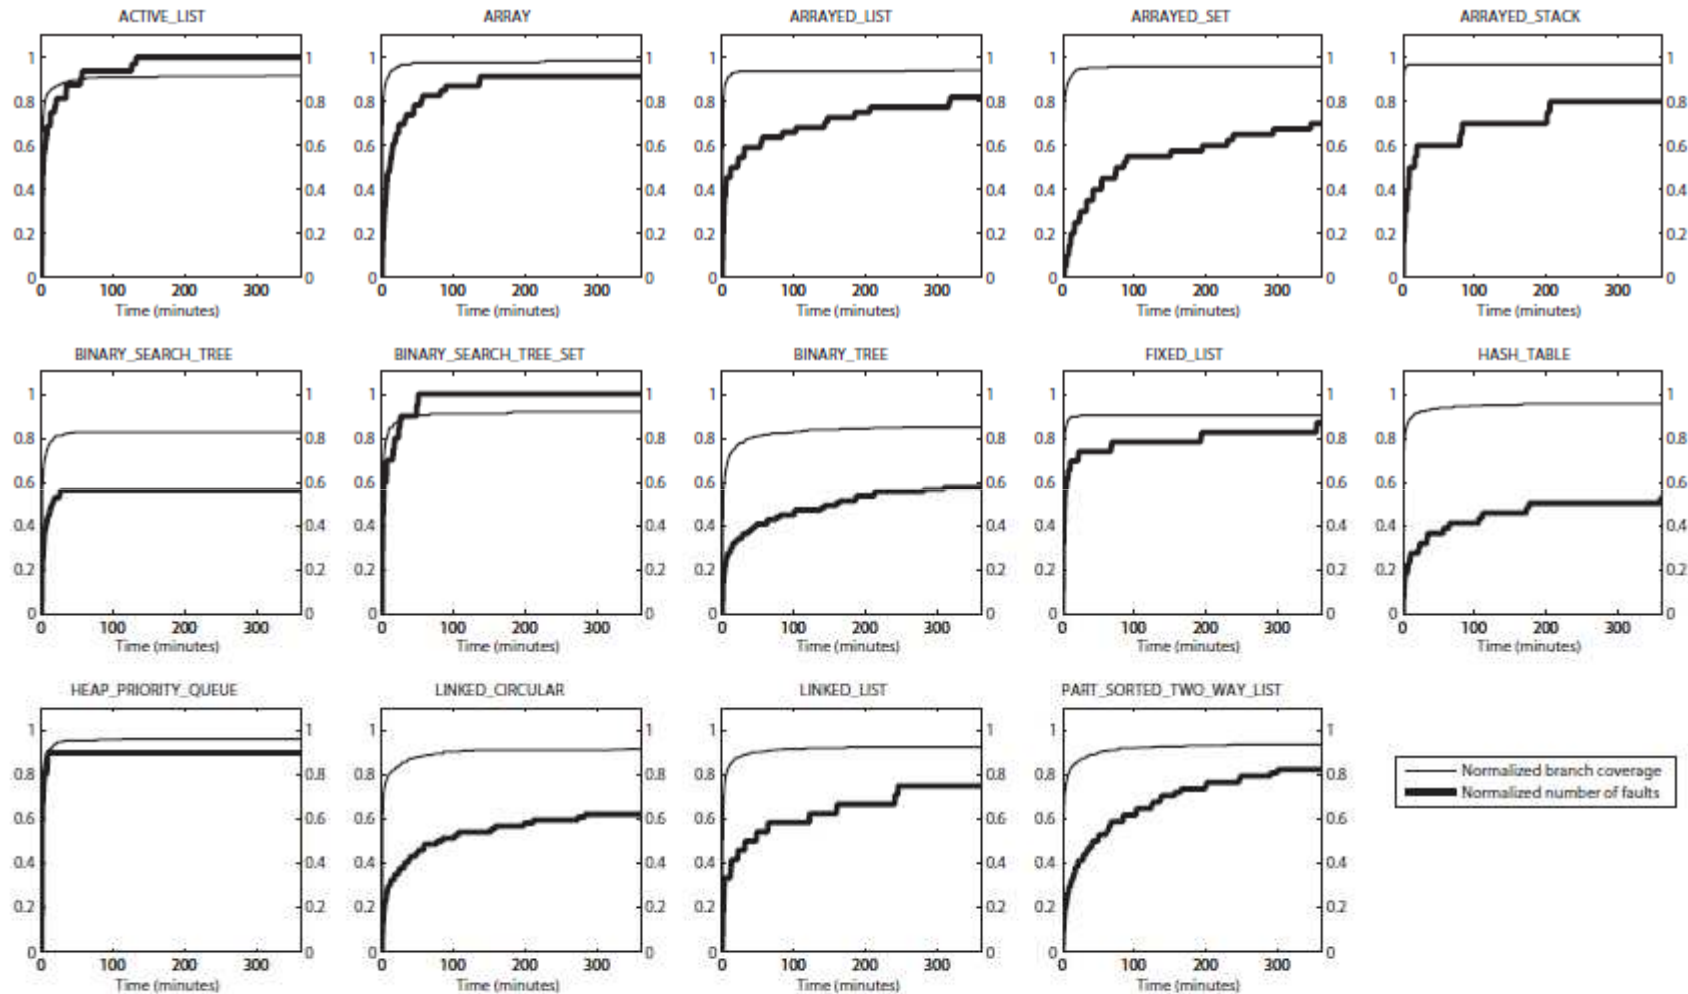

Figure 8: Median of the branch coverage level and median of the normalized number of faults for each class over time

Dataflow-oriented testing

Focuses on how variables are defined, modified, and accessed throughout the run of the program

Looks for faults resulting from wrong paths between a definition of a variable in the code and certain uses of that variable

Access-related potential bugs

Examples:

- Using an uninitialized variable
- Assigning to a variable more than once without an intermediate access
- (C++) Deallocating a variable before it is initialized
- (C++) Deallocating a variable before it is used
- Modifying an object more than once without accessing it

Types of access to variables

Definition (def) : change value of variable (constructor, assignment, procedure)

Use: read value of variable

- Computational use (**c-use**): in a computation
- Predicative uses (**p-use**): in a test
- Kill: instruction that results in a variable being deallocated, undefined, released or no longer visible

Examples:

- `z := x * y` // c-use of `y`; c-use of `x`; def of `z`
- `if x > 0 then ...` // p-use of `x`

Data flow graph

All measures of dataflow coverage are defined in terms of the **data flow graph**

- **Sub-path**: sequence of consecutive nodes
- **Path**: sub-path starting at entry node and ending at exit node

Path properties:

- A sub-path is **def-clear** for a variable v if it contains no definition of v
- A sub-path p starting with a def of variable v is a **du-path** for v if p is def-clear for v except for the first node, and v encounters either a c-use in the last node or a p-use along the last edge of p

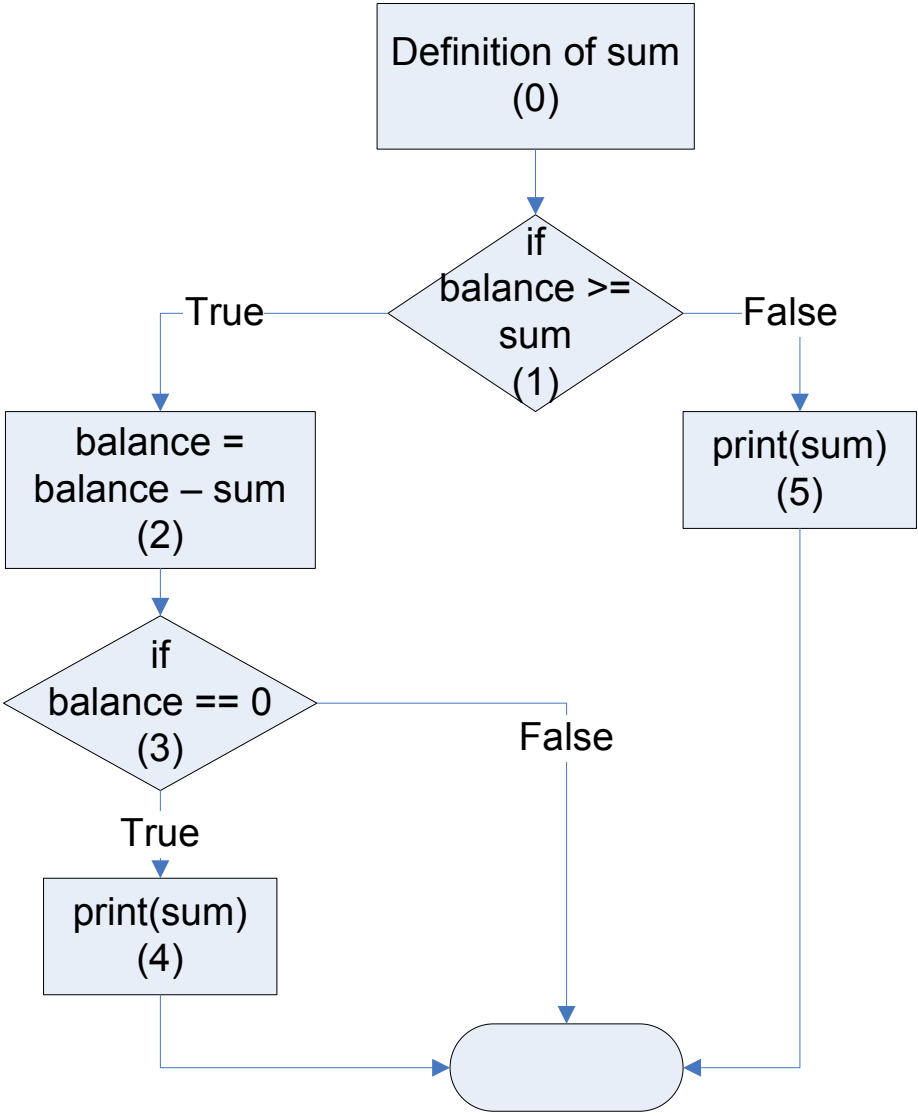

Example: source code

```
class ACCOUNT feature
  balance: INTEGER

  withdraw (sum: INTEGER)
    do
      if balance >= sum then
        balance = balance - sum
        if balance = 0 then
          io.put_string ("There were only " + sum +
            "CHF in the account. The account is now empty.%N")
        end
      else
        io.put_string ("There is less than " + sum + "CHF in the account.")
      end
    end
end
```

Control flow graph for `withdraw`

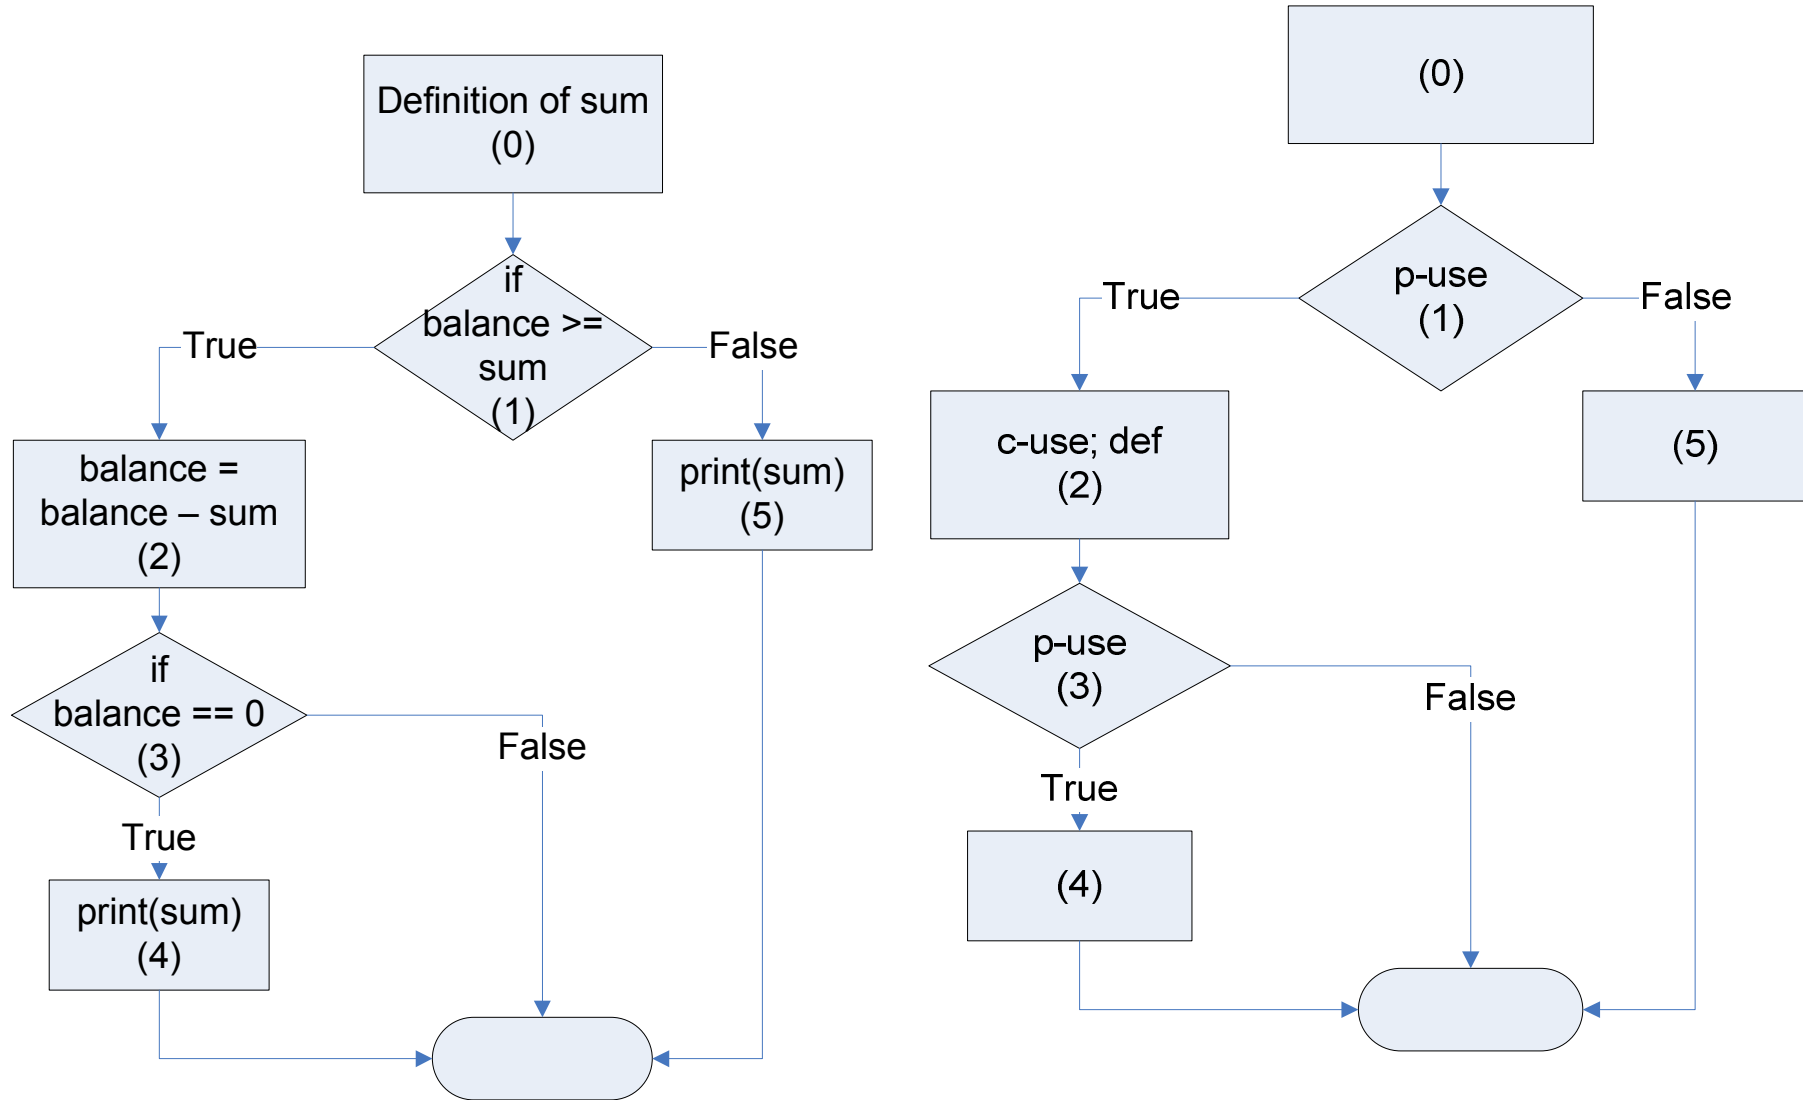

Data flow graph for `sum` in `withdraw`

Data flow graph for `balance` in `withdraw`

Dataflow coverage criteria

all-defs: *execute at least one def-clear sub-path between every definition of every variable and at least one reachable use of that variable.*

all-p-uses: *execute at least one def-clear sub-path from every definition of every variable to every reachable p-use of that variable.*

all-c-uses: *execute at least one def-clear sub-path from every definition of every variable to every reachable c-use of the respective variable.*

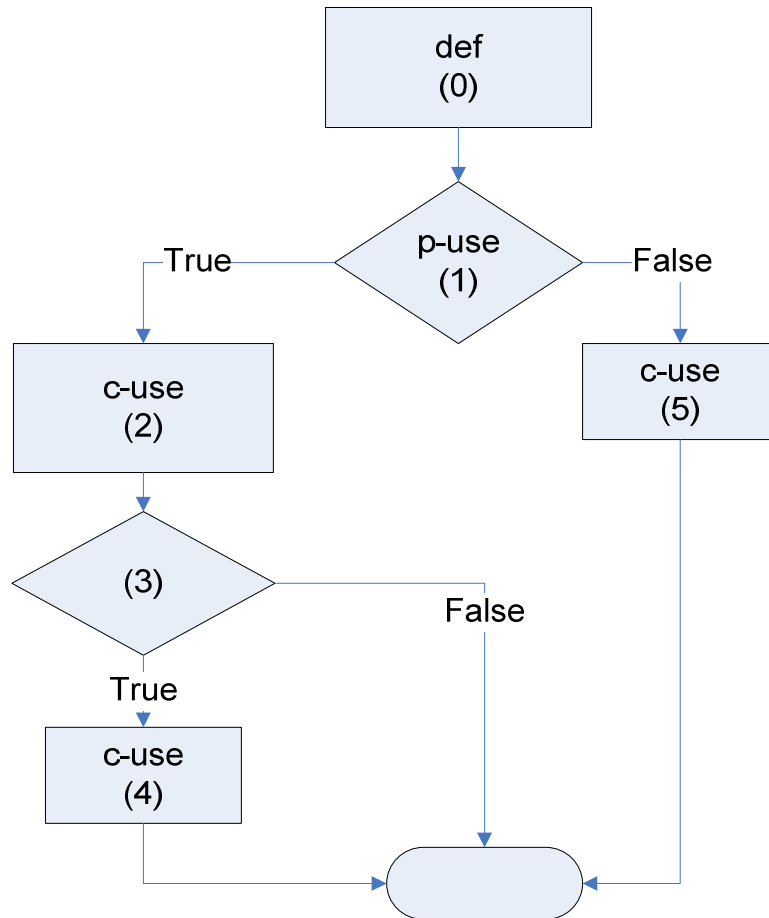

Dataflow coverage criteria (continued)

all-c-uses/some-p-uses: apply all-c-uses; then if any definition of a variable is not covered, use p-use

all-p-uses/some-c-uses: symmetrical to all-c-uses/some-p-uses

all-uses: *execute at least one* def-clear sub-path from *every* definition of every variable to *every* reachable use of that variable

Dataflow coverage criteria for `sum` in `withdraw`

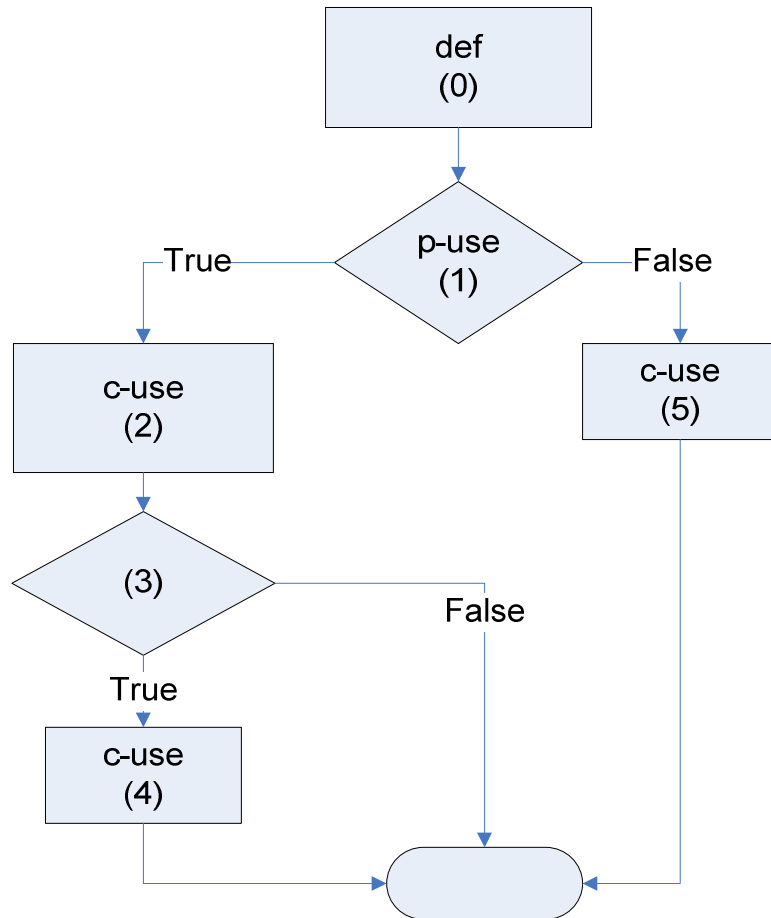

all-defs: *at least one def-clear sub-path between every definition and at least one reachable use*
(0,1)

all-p-uses: *at least one def-clear sub-path from every definition to every reachable p-use*
(0,1)

all-c-uses: *at least one def-clear sub-path from every definition to every reachable c-use*
(0,1,2); (0,1,2,3,4); (0,1,5)

Dataflow coverage criteria for `sum` in `withdraw` (cont.)

all-c-uses/some-p-uses: apply all-c-uses; then if any definition of a variable is not covered, use p-use
(0,1,2); (0,1,2,3,4); (0,1,5)

all-p-uses/some-c-uses: symmetrical to all-c-uses/some-p-uses
(0,1)

all-uses: at least one def-clear sub-path from every definition to every reachable use
(0,1); (0,1,2);(0,1,2,3,4);(0,1,5)

Specification coverage

Predicate: an expression that evaluates to a boolean value

➤ e.g.: $a \vee b \vee (f(x) \wedge x > 0)$

Clause: a predicate that does not contain any logical operator

➤ e.g.: $x > 0$

Notation:

➤ P = set of predicates

➤ C_p = set of clauses of predicate p

If specification expressed as predicates on the state, specification coverage translates to **predicate coverage**

Partition testing

If we cannot test *every* value of the input domain, how do we choose inputs?

A partition divides input space into subsets (**equivalence classes**) satisfying:

- Completeness (covers all input)
- Disjointness

Expectation (hope) behind **partition testing**:

- If any value in the subset produces a failure, any other value in the subset does too

Examples of partition testing

Boundary value analysis

Special values testing

Choosing values

Each Choice (EC):

- Test suite includes at least one test case from every equivalence class for every input

All Combinations (AC):

- Test suite includes at least one test case from every combination of equivalence classes for all inputs

Partition testing

Applicable to *all levels* of testing: unit, class, integration, system, etc.

Based only on the *input space* of the program, not the implementation (i.e. black box concept)

Many testers intuitively apply a similar concept

- 9 -

**Contract-based &
random testing**

Test automation

Testing is so difficult and time consuming...

So why not do it automatically?

What is most commonly meant by "automated testing"
currently is automatic test *execution*

But actually...

What can we automate?

Test execution

- Run test suite without step-by-step actions
- Should be parameterizable
- Recover from failures (multi-process architecture)

Test management

- Let user adapt process to needs and preferences
- Save tests for regression testing

Test result evaluation (applying oracles)

- Classifying tests as pass/no pass
- Other info about test results

What can we automate?

Regression testing

- Re-run previous tests
- May require minimization

Estimation of test suite quality

- Report a measure of code coverage
- Other measures of test quality
- Feed this estimation back to the test generator

Test generation

- Generation of test data (objects used as targets or parameters for feature calls)
- Procedure for selecting the objects used at runtime
- Generation of test code (code for calling the features under test)

“Push-button testing”

Never write a test case, a test suite, a test oracle, or a test driver

Automatically generate

- Objects
- Feature calls
- Evaluation and saving of results

The user must only specify the system under test and the tool does the rest (test generation, execution and result evaluation)

Testing strategy

How do we plan and structure the testing of a large program?

- Who is testing?
 - Developers / special testing teams / customer
 - It is hard to test your own code
- What test levels do we need?
 - Unit, integration, system, acceptance, regression test
- How do we do it in practice?
 - Manual testing
 - Testing tools
 - Automatic testing

xunit

The generic name for any test automation framework for unit testing

- **Test automation framework** - provides all the mechanisms needed to run tests so that only the test-specific logic needs to be provided by the test writer

Implemented in all the major programming languages:

- JUnit - for Java
- cppunit - for C++
- SUnit - for Smalltalk (the first one)
- PyUnit - for Python
- vbUnit - for Visual Basic

JUnit: **resources**

Unit testing framework for Java

Written by Erich Gamma and Kent Beck

Open source (CPL 1.0), hosted on SourceForge

Current version: 4.0

Available at: www.junit.org

Very good introduction for JUnit 3.8: Erich Gamma, Kent Beck, *JUnit Test Infected: Programmers Love Writing Tests*, available at

<http://junit.sourceforge.net/doc/testinfected/testing.htm>

For JUnit 4.0: Erich Gamma, Kent Beck, *JUnit Cookbook*, available at

<http://junit.sourceforge.net/doc/cookbook/cookbook.htm>

JUnit: Overview

Provides a **framework for running test cases**

Test cases

- Written manually
- Normal classes, with annotated methods

Input values and expected results defined by the tester

Execution is the only automated step

How to use JUnit

Requires JDK 5

Annotations:

- `@Test` for every method that represents a test case
- `@Before` for every method that will be executed before every `@Test` method
- `@After` for every method that will be executed after every `@Test` method

Every `@Test` method must contain some check that the actual result matches the expected one - use **asserts** for this

- `assertTrue`, `assertFalse`, `assertEquals`, `assertNull`, `assertNotNull`, `assertSame`, `assertNotSame`

Example: basics

```
package unittests;
```

```
import org.junit.Test; // for the Test annotation
```

```
import org.junit.Assert; // for using asserts
```

```
import junit.framework.JUnit4TestAdapter; // for running
```

```
import ch.ethz.inf.se.bank.*;
```

```
public class AccountTest {
```

```
@Test
```

```
public void initialBalance() {
```

```
    Account a = new Account("John Doe", 2000);
```

```
    Assert.assertEquals(
```

```
        "Initial balance must be the one set through the
```

```
constructor",
```

```
        1000,
```

```
        a.getBalance());
```

```
}
```

```
public static junit.framework.Test suite() {
```

```
    return new JUnit4TestAdapter(AccountTest.class);
```

```
}
```

```
}
```

To declare a routine as a test case

To compare the actual result to the expected one

Required to run JUnit4 tests with the old JUnit runner

Example: set up and tear down

```
package unittests;
```

```
import org.junit.Before; // for the Before annotation  
import org.junit.After; // for the After annotation  
// other imports as before...
```

Must make **account** an attribute of the class now

```
public class AccountTestWithSetUpTearDown {
```

```
    private Account account;
```

To run this routine before any **@Test** method

```
    @Before public void setUp() {  
        account = new Account("John Doe", 30, 1, 1000);  
    }
```

To run this method after any **@Test** method

```
    @After public void tearDown() {  
        account = null;  
    }
```

```
    @Test public void initialBalance() {  
        Assert.assertEquals("Initial balance must be the one set through the  
constructor",  
                             1000,  
                             account.getBalance());  
    }
```

```
    public static junit.framework.Test suite() {  
        return new JUnit4TestAdapter(AccountTestWithSetUpTearDown.class);  
    }  
}
```

```
}
```

@BeforeClass, @AfterClass

A routine annotated with `@BeforeClass` will be executed **once, before** any of the tests in that class is executed.

A routine annotated with `@AfterClass` will be executed **once, after** all of the tests in that class have been executed.

Can have several `@Before` and `@After` routines, but only one `@BeforeClass` and `@AfterClass` routine respectively.

Checking for exceptions

Pass an argument to the `@Test` annotation stating the type of exception expected:

```
@Test(expected=AmountNotAvailableException.class) public void overdraft ()  
throws AmountNotAvailableException {  
    Account a = new Account("John Doe", 30, 1, 1000);  
    a.withdraw(1001);  
}
```

The test will fail if a different exception is thrown or if no exception is thrown.

Setting a timeout

Pass an argument to the `@Test` annotation setting a timeout period in milliseconds. The test fails if it takes longer than the given timeout.

```
@Test(timeout=1000) public void testTimeout () {  
    Account a = new Account("John Doe", 30, 1, 1000);  
    a.infiniteLoop();  
}
```

Testing is tedious!

From a survey of 240 software companies in North America and Europe:

- 8% of companies release software to beta sites **without any testing**.
- 83% of organizations' software developers **don't like** to test code.
- 53% of organizations' software developers don't like to test their own code because they find it **tedious**.
- 30% don't like to test because they find testing **tools inadequate**.

Parts of a test case

Create input

- Instructions

- Data

Execute tests

Evaluate result (Oracle)

- Compare

- Compute

(Tear down)

Degree of automation

No automation

Automated execution

Automated input generation

Automated oracle

Challenges of automated testing

Vast input space

Is this input good?

➤ Precondition

Is this output good?

➤ Postcondition

The quality of the test is only as good as the quality of the assertions

Vast input space

Input space typically
unbounded

Even when finite, very large

Exhaustive testing
impossible

Number of test cases
increases exponentially
with number of input
variables

```
foo (c: CHARACTER)
    do
        ...
    end
bar (c1: CHARACTER;
    c2: CHARACTER)
    do
        ...
    end
```

Automatic testing tools

- TestEra (MIT)
- Korat (MIT)
- AutoTest (ETH)

AutoTest

Fully automated testing framework

- Actual strategies are extensions

Based on Design By Contract

Robust execution

Integration of manual unit tests

AutoTest: three parts

1. *Generated tests*

2. *Extracted tests*

3. *Manual tests*

AutoTest: strategies

Random Strategy

- Use random input

Planning Strategy

- Employ information from postcondition to satisfy preconditions

...

AutoTest: automatic test framework

Ilinca Ciupa
Andreas Leitner
Yi Wei

- Input: set of classes + testing time
- Generates instances, calls routines with automatically selected arguments
- Oracles are contracts:
 - Direct precondition violation: skip
 - Postcondition/invariant violation: bingo!
- Value selection: Random+ (use special values such as 0, +/-1, +/-10, max and min)
- Add manual tests if desired
- Any test (manual or automated) that fails becomes part of the test suite

Minimization through dynamic slicing

```
auto_test system.ace -t 120 ACCOUNT CUSTOMER
```

```
create {STRING} v1  
v1.wipe_out  
v1.append_character ('c')  
v1.append_double (2.45)  
create {STRING} v2  
v1.append_string (v2)  
v2.fill ('g', 254343)  
...  
create {ACCOUNT} v3.make (v2)  
v3.deposit (15)  
v3.deposit (100)  
v3.deposit (-8901)  
...
```

```
class  
  ACCOUNT  
create  
  make  
feature  
  make (n: STRING)  
  require  
    n /= Void  
  do  
    name := n  
    balance := 0  
  ensure  
    name = n  
    balance = 0  
end
```

```
name: STRING  
balance: INTEGER  
deposit (v: INTEGER)  
  do  
    balance := balance + v  
  ensure  
    balance =  
      old balance + v  
  end  
invariant  
  name /= Void  
  balance >= 0  
end
```

AutoTest strategies

- Object pool
 - Get objects through creation procedures (constructors)
 - Diversify through procedures
- Routine arguments
 - Basic values: heuristics for each type
 - Objects: get from pool
- Test all routines, including inherited ones (“Fragile base class” issue)

Adaptive Random Testing (Chen et al.)

Conjecture:

Random testing may find faults faster if inputs evenly spread

So far: basic types

Our contribution: extend this to objects

Need to define notion of **distance** between objects

Object distance

Ilinca Ciupa
(ICSE 2007)

$p \leftrightarrow q \triangleq$

combination (

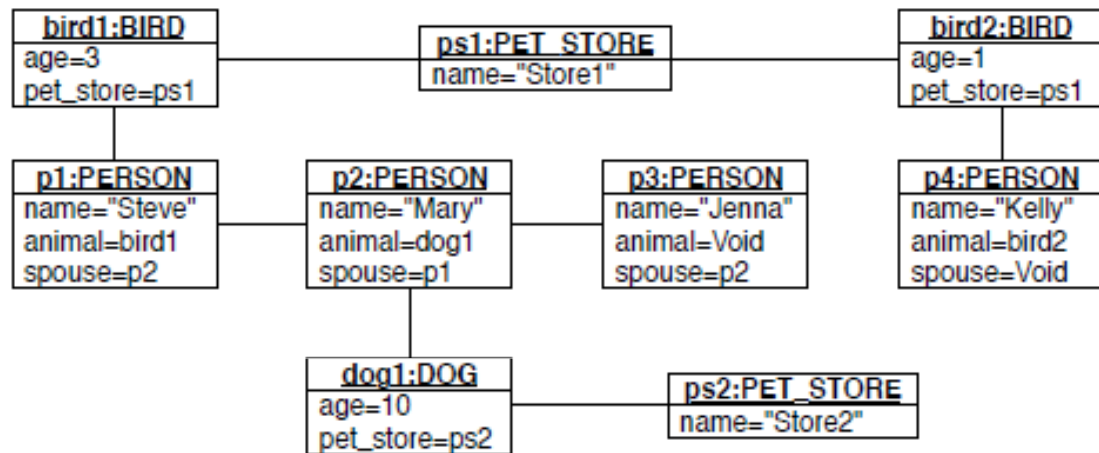

type_distance (p.type, q.type),

field_distance (p, q),

recursive_distance (

$\{[p.r \leftrightarrow q.r] \mid r \in$

Reference_attributes})

ART vs pure random

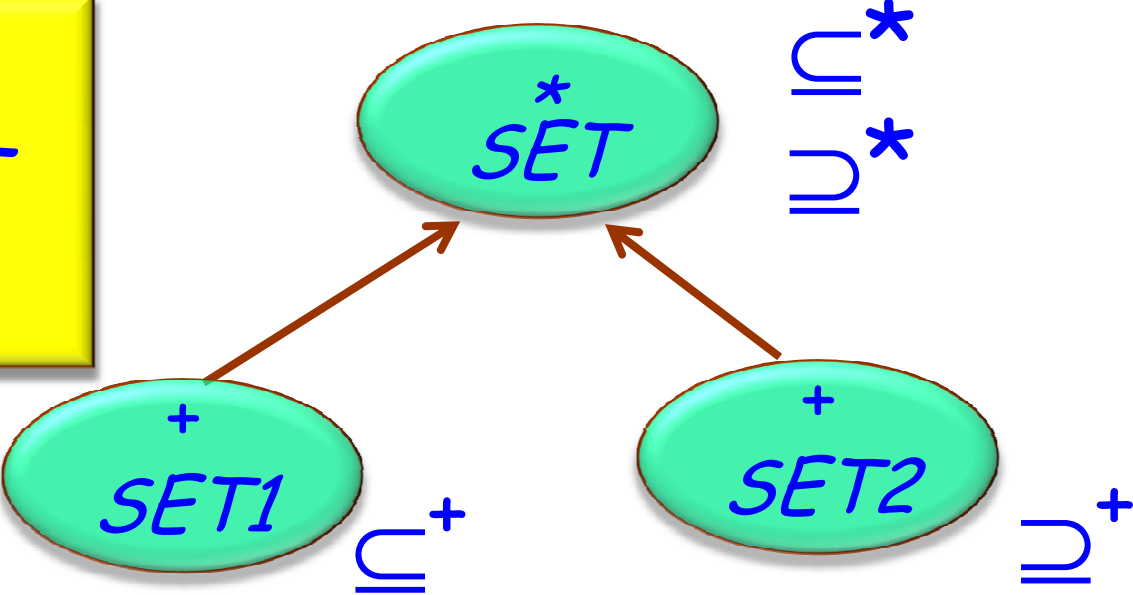

Results so far:

- Does not find more faults
- Does not find faults faster
- Finds **other** faults!

Random testing: example bug found

Bernd Schoeller

Test:
 $s1, s2: SET$
 $s2 \subseteq s1$

*: Deferred
+: Effective

The testbed: EiffelBase

- Version of September 2005
- 20-year history
- Showcase of Eiffel technology
- About 1800 classes, 20,000 SLOC
- Extensive (but not complete) contracts
- Widely used in production applications
- Significant faults remained

Some AutoTest results (random strategy)

Library	TESTS		ROUTINES	
	Total	Failed	Total	Failed
EiffelBase (Sep 2005)	40,000	3%	2000	6%
Gobo Math	1500	1%	140	6%

Testing results and strategy

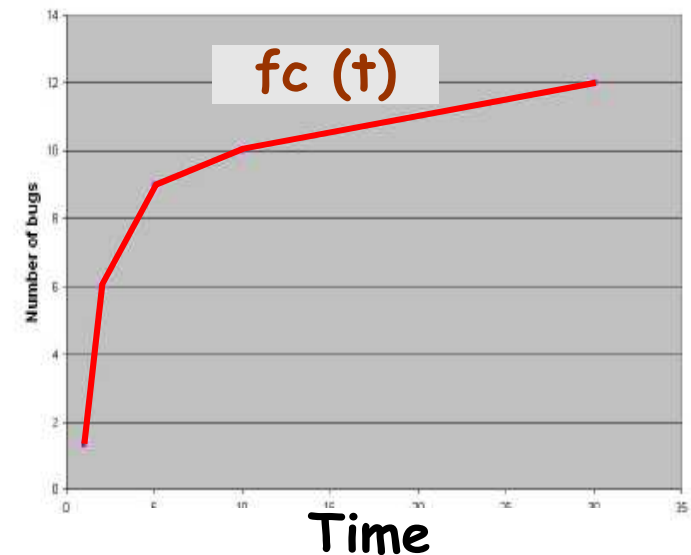

“Smart” ideas not always better
Don't believe your intuition
Measure and assess objectively

Define good assessment criteria:

- Number of faults found
- Time to find all faults

Class *STRING*

Experimental law:

$$fc(t) = a / (1 + b * t)$$

Fault categories

Specification faults -- examples:

- Precondition:
 - Missing non-voidness precondition (will go away)
 - Missing min-max precondition
 - Too strong precondition
- Postcondition:
 - Missing
 - Wrong

Implementation faults -- examples:

- Faulty supplier
- Missing implementation
- Case not treated
- Violating a routine's precondition
- Infinite loop

Who finds what faults?

I.Ciupa, A. Leitner,
M.Oriol, A. Pretschner
(submitted)

On a small EiffelBase subset,
we compared:

- AutoTest
- Manual testing (students) (3 classes, 2 with bugs seeded)
- User reports from the field

AutoTest: 62% specification, 38% implementation

User reports: 36% specification, 64% implementation

AutoTest vs manual testers

On three classes (two with seeded bugs):

- Humans found 14 faults, AutoTest 9 of them
- AutoTest found 2 faults that humans did not (in large class)
- 3 faults not found by AutoTest found by 60% of humans (one is infinite loop)
- 2 faults not found by AutoTest are missing preconditions (void, min-max)

AutoTest vs user reports

On 39 EiffelBase classes:

- AutoTest found 85 faults,
Plus 183 related to RAW_FILE,
PLAIN_TEXT_FILE, DIRECTORY (total 268)
- 4 of these also reported by users
- 21 faults solely reported by users
- 30% of AutoTest-found bugs related to extreme values;
users never report them

AutoTest finds only 1 out of 18 (5%) of implementation faults
and 3 out of 7 specification faults

AutoTest bad at over-strong preconditions, wrong operator
semantics, infinite loops, missing implementations

Users never find faulty suppliers (blame on client)

AutoTest developments

- Large-scale extensive tests, empirical assessment of criteria & strategies
- Comparison with manual efforts
- Complete integration with EiffelStudio IDE
- Background, unobtrusive, continuous testing
- Distributed cooperative testing ("Testi@home")

Test Extraction

Andreas Leitner, Arno Fiva

Like Test-Driven Development, but

- Tests derived from spec (contracts)
- Not the other way around!

Record every failed execution, make it reproducible by retaining objects

Turn it into a regression test

Specified but unimplemented routine

The screenshot shows an Eclipse IDE window titled "BANK_ACCOUNT in cluster root_cluster located in /home/aleitner/eclipse/cdd_es/Src/examples/cdd/bank_account/./bank_a". The editor displays the following code:

```
class
  BANK_ACCOUNT

inherit
  ANY

  redefine
    default_create
  end

deposit (an_amount: INTEGER) is
  do
  ensure
    balance_increased: balance > old balance
    deposited: balance = old balance + an_amount
  end

withdraw (an_amount: INTEGER) is
  do
  ensure
    balance_decreased: balance < old balance
    withdrawn: balance = old balance + an_amount
  end

invariant
  balance_not_negativ: balance >= 0
```

The "deposit" routine is highlighted in a green box with a red border. Below it, two smaller boxes show the "deposited" condition and the "withdraw" routine. The "deposited" condition is shown in a green box with a red border, and the "withdraw" routine is shown in a blue box with a red border. The "invariant" section is shown in a white box with a red border.

Running the system and entering input

(erroneous)

The screenshot shows a window titled "My Bank Account" with a standard OS title bar (minimize, maximize, close buttons). The main content area displays "Current Balance: 300". Below this is a text input field containing the number "20". A mouse cursor is positioned over the input field. Underneath the input field are two large, light-colored buttons: "Deposit" and "Withdraw". The "Deposit" button is highlighted with a dashed border. The "Withdraw" button is below it. The bottom of the window is empty.

Error caught at run time as contract violation

Postcondition violated

balance increased: $balance > old\ balance$
deposited: $balance = old\ balance + an_amount$

The violated clause:
balance > old balance

My Bank Account
Current Balance: 300
Withdraw

This has become a test case

The screenshot shows the Eclipse IDE interface. The main editor displays code for a feature, with a tooltip over the 'Start' button indicating 'Start application and stop at breakpoints (F5)'. The 'Test Cases' view shows a tree structure with 'root_cluster' expanded to show 'BANK_ACCOUNT', which contains a test case 'deposit' marked with a red 'F' for failure. A red arrow points from the 'deposit' test case in the 'Test Cases' view to the 'deposit' test case in the 'Test Cases' view at the bottom of the IDE.

```
end

Correcting and recompiling

The screenshot shows the Eclipse IDE interface for an Eiffel project. The title bar indicates the current file is `{BANK_ACCOUNT}.deposit` located in `/home/aleitner/eclipse/cdd_es/Src/examples/cdd/b`. The menu bar includes File, Edit, View, Favorites, Project, Debug, Refactoring, Tools, Window, and Help. The toolbar contains various icons, with the 'Compile' button (represented by a document with a lightning bolt) highlighted by a yellow box. Below the toolbar, the 'Compile current project (F7)' button is also highlighted. The left sidebar shows the project structure under 'Clusters', with 'root_cluster' expanded to show 'APPLICATION', 'BANK_ACCOUNT', 'INTERFACE_NAMES', and 'MAIN_WINDOW'. Below this, 'Libraries' includes 'bank_account'. The main editor displays the source code for the `deposit` and `withdraw` methods, along with an invariant. The `deposit` method increments the balance, and the `withdraw` method decrements it. The invariant ensures the balance is non-negative. The bottom status bar shows 'Eiffel Compilation Succeeded'. A yellow oval highlights the 'Context' pane, which shows the current context as `root_cluster BANK_ACCOUNT withdraw`. A purple oval highlights the 'Test Cases' pane, which shows two test cases: 'Test case #01' and 'Test case #02', both with a question mark next to them. The bottom status bar also shows 'Eiffel Compilation Succeeded'.

```
deposit (an_amount: INTEGER) is
do
  balance := balance + an_amount
ensure
  balance_increased: balance > old balance
  deposited: balance = old balance + an_amount
end

withdraw (an_amount: INTEGER) is
do
ensure
  balance_decreased: balance < old balance
  withdrawn: balance = old balance + an_amount
end

invariant
  balance_not_negativ: balance >= 0

end
```

Context: root_cluster BANK_ACCOUNT withdraw

Compiling Interpreter

Eiffel Compilation Succeeded

One fault corrected, the other not

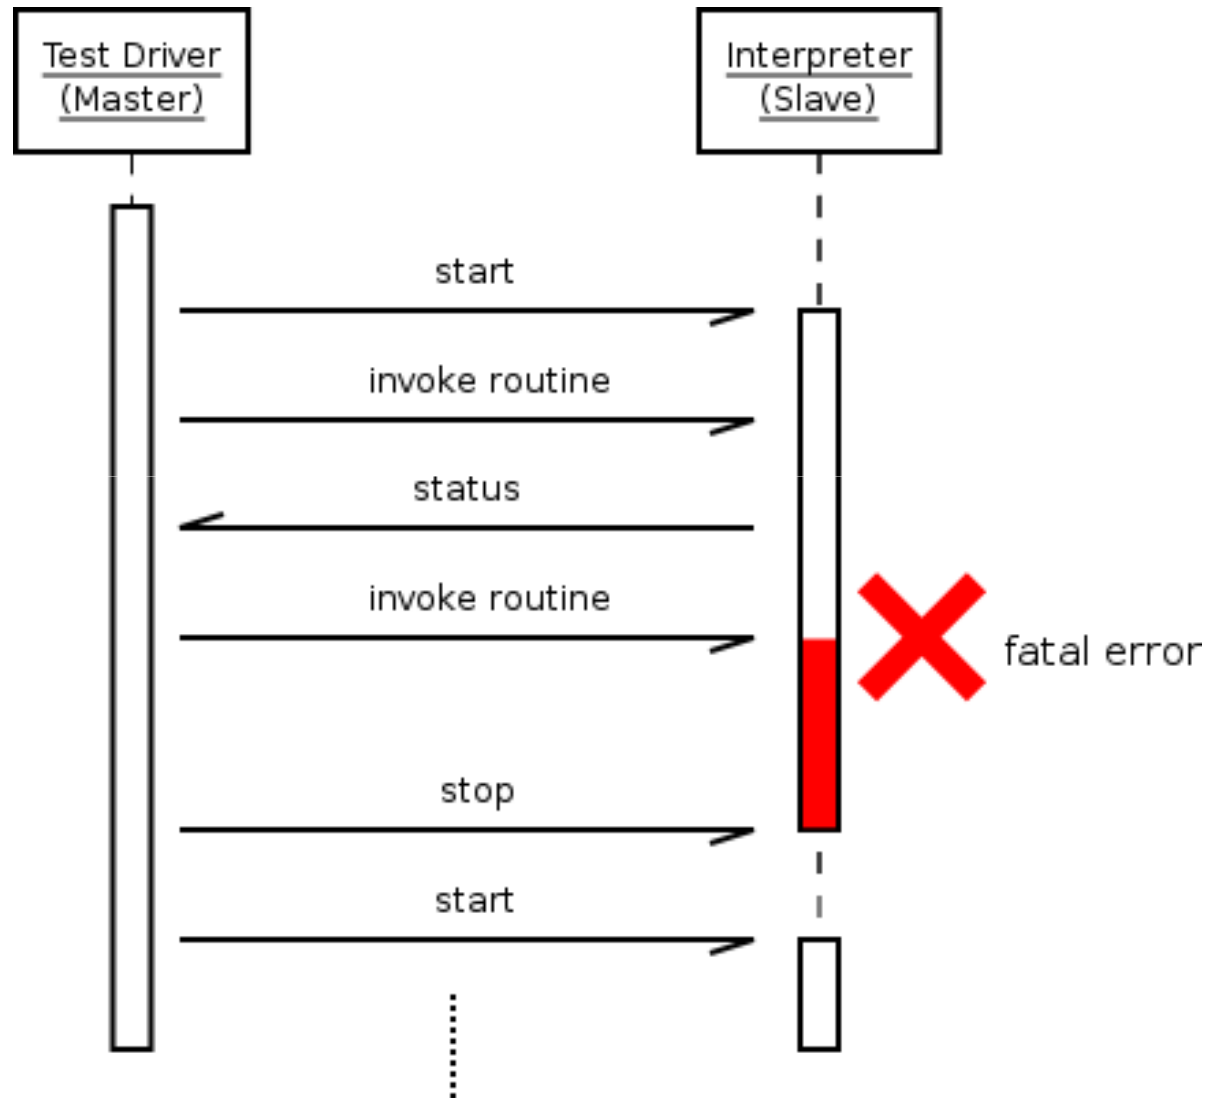

The screenshot displays the Eclipse IDE interface with the following components:

- Editor:** Shows the source code for `{BANK_ACCOUNT}.deposit`. The code includes a `do` block with `ensure` and `end` keywords, and an `invariant` block.
- Clusters View:** Shows a tree structure with `root_cluster` containing `APPLICATION`, `BANK_ACCOUNT`, `INTERFACE_NAMES`, and `MAIN_WINDOW`.
- Libraries View:** Shows the `bank_account` library.
- Testing Window:** Displays test results for `root_cluster` and `BANK_ACCOUNT`.

Test Case	Result
Test case #01	OK
Test case #02	F
- Context Window:** Shows compilation output: "Degree 6: Exam...", "Degree 5: Parsing Classes", "Degree 4: Analyzing Inheritance", "Degree 3: Checking Types", "Degree 2: Generating Byte Code", "Degree 1: Generating Metadata", "Melting System Changes", "There were 12 warnings during compilation.", "Eiffel Compilation Succeeded". A red arrow points from the 'F' result in the Testing window to this window.
- Output Window:** Shows "Eiffel Compilation Succeeded".
