Chair of Software Engineering

Static verification of Eiffel programs using Boogie

Julian Tschannen

Chair of Software Engineering

ETH Zürich

Topics

- Overview
- Translation
  - Types and inheritance
  - Heap model and object creation
  - Routines and frame conditions
  - Generics
  - Dynamic contracts

Overview

- Static verification of a subset of Eiffel
- Part of EVE (Eiffel Verification Environment)
- Covers:
  - Assignment, loops, routine calls, object creation
  - Integer arithmetic, boolean arithmetic
  - Agents
- Not covered:
  - Exception handling, once routines
  - Expanded types, floating point arithmetic

Workflow

- Translates AST from EiffelStudio to Boogie
- Uses Boogie verifier to check Boogie files
- Traces verification errors back to Eiffel source

Boogie file layout

- Background theory
  - Definitions and axioms
- Proven classes
  - Type definition
  - Routine signatures
  - **Routine implementations (this is proven)**
- Referenced routines
  - Routine signature

Demo

- User interface
- Account
- Generated Boogie file

Translating Eiffel to Boogie

- Types and inheritance
- Heap model and object creation
- Routines and frame conditions
- Generics
- Dynamic contracts

Encoding types

- Boogie type for Eiffel types

```
type Type;
```

- Type declaration

```
const unique ACCOUNT: Type;
```

- Encoding inheritance

```
axiom ACCOUNT <: ANY;
```

- Encoding multiple inheritance

```
axiom ARRAYED_LIST <: ARRAY;
axiom ARRAYED_LIST <: LIST;
```

References and the heap

- Reference type

```
type ref;                    const Void: ref;
```

- Generic field type

```
type Field _;
```

- The heap type is a mapping from **references** and **fields** to generic **values**

```
type HeapType = <beta>[ref, Field beta]beta;
```

- The heap is a global variable

```
var Heap: HeapType
```

Ghost fields and attributes

- Ghost field to store allocation status of objects

```
const unique $allocated: Field bool;
```

- Ghost field to store type of objects

```
const unique $type: Field Type;
```

- Field declaration for each attribute
- Generic field type instantiated with Eiffel type

```
const unique field.ACCOUNT.balance: Field int;
```

Using the heap

- Functions and axioms using heap

```
function IsAllocated(heap: HeapType, o: ref)
   returns (bool);

axiom (forall heap: HeapType, o: ref ::
   IsAllocated(heap, o) <==> heap[o, $allocated]);
```

- Assignment to attribute

```
implementation create.ACCOUNT.make(Current: ref) {
  Heap[Current, field.ACCOUNT.balance] := 0;
}
```

Creating objects on the heap

- Allocate a **fresh** reference on Heap
- Set type and call creation routine

```
implementation {
  var temp_1;
entry:
  havoc temp_1;
  assume (temp_1 != Void) &&
                          (!Heap[temp_1, $allocated]);
  Heap[temp_1, $allocated] := true;
  Heap[temp_1, $type] := ACCOUNT;
  call create.ACCOUNT.make(temp_1);
}
```

Routine signatures

- Signature consists of
  - Arguments
  - Contracts
  - Frame condition

```
deposit (amount: INTEGER)
      require
            amount >= 0
      ensure
            balance = old balance + amount
      end

invariant
      balance >= 0
```

Encoding routine signatures

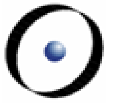
```
procedure proc.ACCOUNT.deposit(
            Current: ref,
            arg.amount: int);
  // Precondition and postcondition
  requires arg.amount >= 0;
  ensures Heap[Current, field.ACCOUNT.balance] ==
      old(Heap[Current, field.ACCOUNT.balance]) +
      arg.amount;
  // Invariant
  free requires Heap[Current, field.ACCOUNT.balance] >= 0;
  ensures Heap[Current, field.ACCOUNT.balance] >= 0;
  // Frame condition
  modifies Heap;
  ensures (forall<alpha> $o: ref, $f: Field alpha ::
     $o != Void && IsAllocated(old(Heap), $o) &&
     (!($o == Current && $f == field.ACCOUNT.balance))
      ==> (old(Heap)[$o, $f] == Heap[$o, $f]));
```

Frame condition

- Describe effect of a routine on heap
- Important for modular proofs

- Different ways to express frame condition
  - Modifies clauses
  - Separation logic
  - Ownership types
  - …

Frame condition in Eiffel

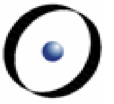


- Modifies clauses
  - What attributes a routine may modify
  - Needs change to Eiffel language

```
deposit (amount: INTEGER)
        require
                amount >= 0
        ensure
                balance = old balance + amount
        modify
                balance
        end
```

- Automatic extraction of modifies clause
  - All attributes mentioned in postcondition

Encoding frame conditions



- Modify whole heap
- Express unchanged parts for each routine

```
procedure proc.ACCOUNT.deposit(
            Current: ref, arg.amount: int);
  modifies Heap;
  ensures (
    forall<alpha> $o: ref, $f: Field alpha ::
      $o != Void &&
      IsAllocated(old(Heap), $o) &&
      (!($o == Current && $f == field.ACCOUNT.balance))
        ==>
      (old(Heap)[$o, $f] == Heap[$o, $f])
  );
```

Pure functions

- Functions which have no side-effects
- Partial automation of detecting pure functions
  - Each function that is used in a contract
- Functions can be marked as pure
- Purity is checked by Boogie
- Simple encoding

```
procedure proc.ARRAY.length(Current: ref)
  modifies Heap;
  ensures Heap == old(Heap);
```

Generics

- Distinguish between **definition** of generic classes and **use** of generic routines
- Replace generics with a semantic equivalent
  - For each generic class, replace generic parameter with its constraint
  - For each generic routine, create routine signature for each derivation used
  - When a generic routine is used, use signature of specific derivation

Generic classes

```
class CELL [G -> ANY]
feature
	item: G
	set_item (a_item: G)
		do
			item := a_item
		ensure
e
```

```
class CELL
feature
	item: ANY
	set_item (a_item: ANY)
		do
			item := a_item
		ensure
			item = a_item
		end
end
```

Generic routines used

```
local
        l_cell1: CELL [STRING]
        l_cell2: CELL [INTEGER]
do
        create l_cell1; l_cell1.set_item ("abc")
        create l_cell2; l_cell2.set_item (7)
end
```

```
procedure proc.CELL#STRING#.set_item(
```

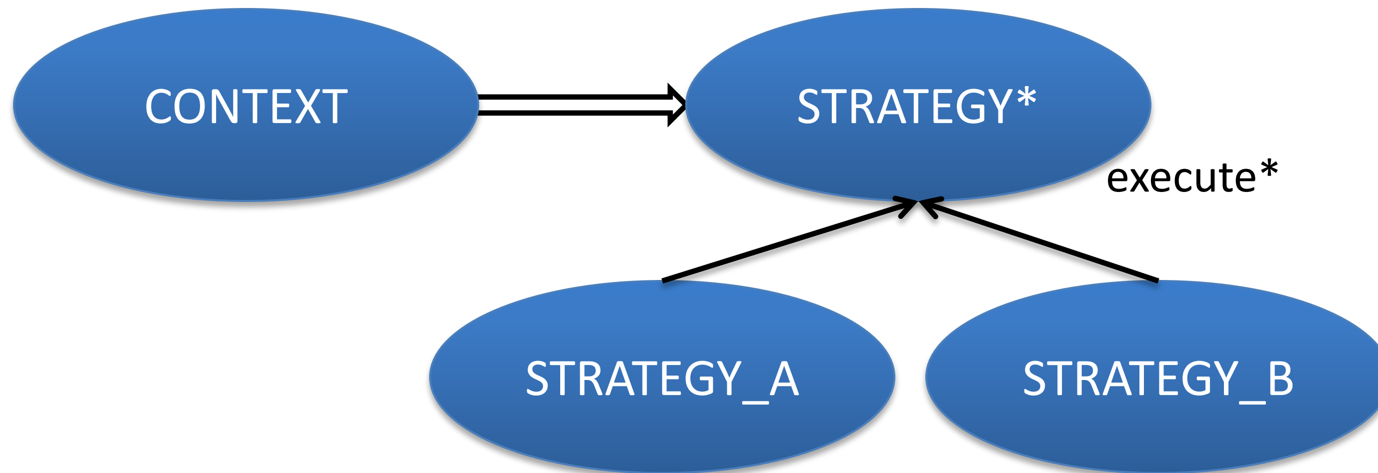
```
procedure proc.CELL#INTEGER#.set_item(
            Current: ref,
            arg.a_item: int
        );
    ensures Heap[Current, field.CELL#INTEGER#.item]
                                    == arg.a_item;
    modifies Heap;
    ensures <<frame condition>>;
```

Dynamic contracts

- Dynamic type might have different contract than static type
  - Weaker precondition
  - Stronger postcondition
- If dynamic type is known, we can use the **dynamic contract** for the proof
- We use **abstract predicates** to encode dynamic contracts

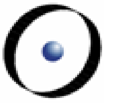
Motivating example

- Strategy pattern



- Implementations of *execute* strengthen postcondition to express their behavior
- Demo

Encoding parent postcondition



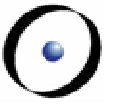
- Define abstract postcondition predicate
- Link predicate to actual postcondition depending on type

```
function post.STRATEGY.execute(h1, h2, current)
    returns (bool);

procedure proc.STRATEGY.execute(Current: ref);
    ensures post.STRATEGY.execute(
                                Heap, old(Heap), Current)

axiom (forall h1, h2, current ::
    h1[current, $type] <: STRATEGY ==>
    (post.STRATEGY.execute(h1, h2, current) ==>
        <<parent postcondition>>));
```

Encoding child postcondition



- Link predicate for parent postcondition to strengthened postcondition for child type

```
axiom (forall h1, h2, current ::
    h1[current, $type] <: STRATEGY_A ==>
    (post.STRATEGY.execute(h1, h2, current) ==>
        <<child postcondition>>));
```

- For a child object, the abstract postcondition predicate will imply both postconditions

Encoding dynamic preconditions

- Inverse implication: actual precondition implies precondition predicate

```
function pre.STRATEGY.execute(h1, current)
    returns (bool);

procedure proc.STRATEGY.execute(Current: ref);
    requires pre.STRATEGY.execute(Heap, Current)

axiom (forall h1, current ::
    h1[current, $type] <: STATEGY ==>
    (<<parent precondition>> ==>
        pre.STRATEGY.execute(h1, current) ));
```

Call site example

```
implementation {
  var s: ref;
entry:
  assume Heap[s, $allocated] && s != Void;
  assume Heap[s, $type] == STRATEGY_A;

  // call proc.STRATEGY.execute(s);
  assert pre.STRATEGY.execute(Heap, s);
  h_old := Heap;
  havoc Heap
  assume <<frame condition>>;
  assume post.STRATEGY.execute(Heap, h_old, s);

  assert <<child postcondition>>;

}
```

Conclusions

- Different ways of translation
  - Mapping Eiffel semantics to Boogie
  - Eiffel side source-to-source translation
- Needs full translation to prove full programs
  - Expanded types missing
  - Exceptions missing
- Modularity of proofs allows to partially prove a program

Theses

- You can do your master’s thesis, bachelor’s thesis or a semester thesis with us
- Topics:
  - **Verification of object-oriented programs**
  - **Verification debugger**
- Contact me:
