

# Einführung in die Programmierung Introduction to Programming

Prof. Dr. Bertrand Meyer

Exercise Session 5

- Attributes, formal arguments, and local variables
- Control structures

Declared anywhere inside a feature clause, but outside other features

```
class C  
feature
```

```
  attr1 : CA1
```

```
  f (arg1 : A ...)
```

```
    do
```

```
      ...
```

```
    end
```

```
...
```

```
end
```

Visible anywhere inside the class

visible outside the class (depending on their visibility)

# Formal arguments

---

Declared after the feature name, in parenthesis:

**feature**

```
f (arg1 : C1 ; ... ; argn : CN )
```

```
    require ...
```

```
    local
```

```
        ...
```

```
    do
```

```
        ...
```

```
    ensure ...
```

```
end
```

only visible inside the feature body and its contracts

# Local variables

Some variables are only used by a certain routine.

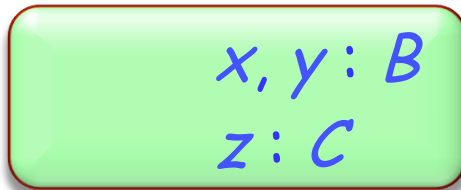

Declare them as local:

**feature**

*f* (*arg1*: *A* ...)

**require** ...

**local**

*x, y*: *B*  
*z*: *C*

**do**

...

**ensure** ...

**end**

only visible inside the feature body

## Attributes:

- declared anywhere inside a feature clause, but outside other features
- visible anywhere inside the class
- visible outside the class (depending on their visibility)

## Formal arguments:

- declared after the feature name, in parenthesis
- only visible inside the feature body and its contracts

## Local variables:

- declared in a local clause inside the feature declaration
- only visible inside the feature body

# Compilation error? (1)

Hands-On

```
class PERSON
feature
  name : STRING

  set_name (a_name : STRING)
  do
    name := a_name
  end

  exchange_names (other : PERSON)
  local
    s : STRING
  do
    s := other.name
    other.set_name (name)
    set_name (s)
  end

  print_with_semicolon
  do
    create s.make_from_string (name)
    s.append (";")
    print (s)
  end
end
```

Error: this variable was not declared

# Compilation error? (2)

Hands-On

```
class PERSON
feature
```

```
...      -- name and set_name as before
```

```
exchange_names(other : PERSON)
```

```
  local
```

```
    s : STRING
```

```
  do
```

```
    s := other.name
```

```
    other.set_name(name)
```

```
    set_name(s)
```

```
  end
```

```
print_with_semicolon
```

```
  local
```

```
    s : STRING
```

```
  do
```

```
    create s.make_from_string(name)
```

```
    s.append(";")
```

```
    print(s)
```

```
  end
```

```
end
```

OK: two different local variables in two routines

# An example of side effects

Hands-On

```
class PERSON
```

```
feature
```

```
  ...  
  name : STRING
```

```
  print_with_semicolon
```

```
    local
```

```
      s : STRING
```

```
    do
```

```
      create s.make_from_string (name)
```

```
      s.append(";")
```

```
      print (s)
```

```
    end
```

```
  print_with_sticky_semicolon
```

```
    do
```

```
      name.append(";")
```

```
      print (name)
```

```
    end
```

```
end
```

Now the semicolon sticks to the attribute.

This is called side effect

Remember that strings in Eiffel are mutable!

# Compilation error? (3)

Hands-On

```
class PERSON
feature
  ...      -- name and set_name as before

  s: STRING

  exchange_names (other : PERSON)
  do
    s := other.name
    other.set_name (name)
    set_name (s)
  end

  s: STRING

  print_with_semicolon
  do
    create s.make_from_string (name)
    s.append (“;”)
    print (s)
  end

end
```

Error: an attribute with the same name was already defined

# Compilation error? (4)

Hands-On

```
class PERSON
```

```
feature
```

```
...      -- name and set_name as before
```

```
exchange_names (other : PERSON)
```

```
do
```

```
    s := other.name
```

```
    other.set_name (name)
```

```
    set_name (s)
```

```
end
```

```
print_with_semicolon
```

```
do
```

```
    create s.make_from_string (name)
```

```
    s.append (';')
```

```
    print (s)
```

```
end
```

```
s : STRING
```

```
end
```

OK: a single attribute  
used in both routines

# Local variables vs. attributes

---

Hands-On

- Which one of the two correct versions (2 and 4) do you like more? Why?
- Describe the conditions under which it is better to use a local variable instead of an attribute and vice versa

- Inside every function you can use the predefined local variable **Result** (you needn't and shouldn't declare it)
- The return value of a function is whatever value the **Result** variable has at the end of the function execution
- At the beginning of routine's body **Result** (as well as regular local variables) is initialized with the default value of its type
- Every regular local variable is declared with some type; and what is the type of **Result**?

It's the function return type!

# Compilation error? (5)

Hands-On

```
class PERSON
feature
```

```
...      -- name and set_name as before
exchange_names (other : PERSON)
do
    Result := other.name
    other.set_name (name)
    set_name (Result)
end
```

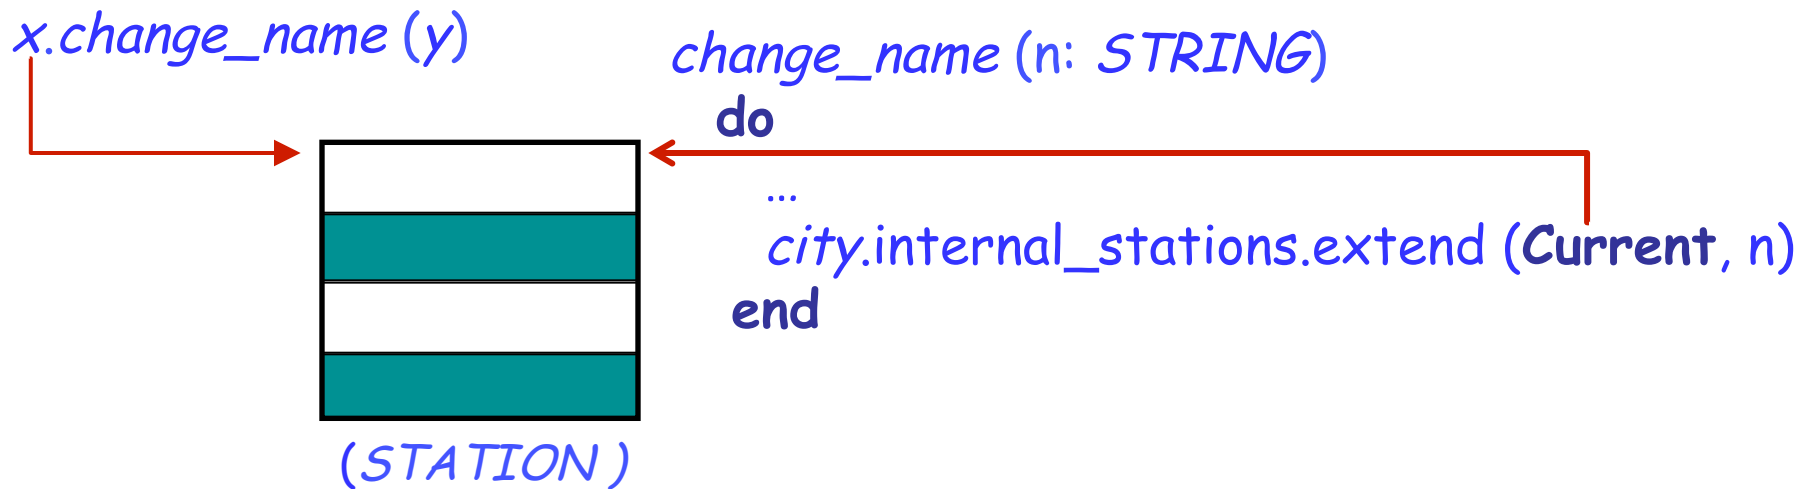

Error: Result can not be used in a procedure

```
name_with_semicolon : STRING
```

```
do
    create Result.make_from_string (name)
    Result.append ( ';' )
    print (Result)
end
```

```
end
```

- In object-oriented computation each routine call is performed on a certain object
- From inside a routine we can access this object using the predefined entity **Current**

- What is the type of **Current**?

- If the target of a feature call is **Current**, it is omitted:

$\text{Current.f}(a)$   
 $f(a)$

- Such a call is **unqualified**
- Otherwise, if the target of a call is specified explicitly, the call is **qualified**

$x.f(a)$

# Qualified or unqualified?

Hands-On

Are the following feature calls, with their feature names underlined, qualified or unqualified?  
What are the targets of these calls?

1)  $x.\underline{y}$

qualified

2)  $\underline{x}$

unqualified

3)  $\underline{f}(x.a)$

unqualified

4)  $x.\underline{y}.z$

qualified

5)  $\underline{x}(y.f(a.b))$

unqualified

6)  $f(x.a).\underline{y}(b)$

qualified

7) **Current.** $\underline{x}$

qualified

# Assignment to attributes

- Direct assignment to an attribute is only allowed if an attribute is called in an unqualified way:

`y := 5`

OK

`x.y := 5`

Error

`Current.y := 5`

Error

- There are two main reasons for this rule:
  1. A client may not be aware of the restrictions on the attribute value and interdependencies with other attributes => class invariant violation (Example?)
  2. Guess! (Hint: uniform access principle)

# Constant attributes

- It is possible to declare constant attributes, that is, attributes having a fixed value that cannot change during the program execution.

```
class CAR  
feature
```

```
...
```

```
...
```

```
number_of_gears: INTEGER = 5
```

Constant attribute

```
...
```

```
set_number_of_gears (new_number: INTEGER)
```

```
do
```

```
    number_of_gears := new_number
```

```
end
```

Error: constant attributes are readonly

```
end
```

# Entity: the final definition

An **entity** in program text is a “name” that *directly* denotes an object. More precisely: it is one of

➤ attribute name

➤ variable attribute

➤ constant attribute

➤ formal argument name

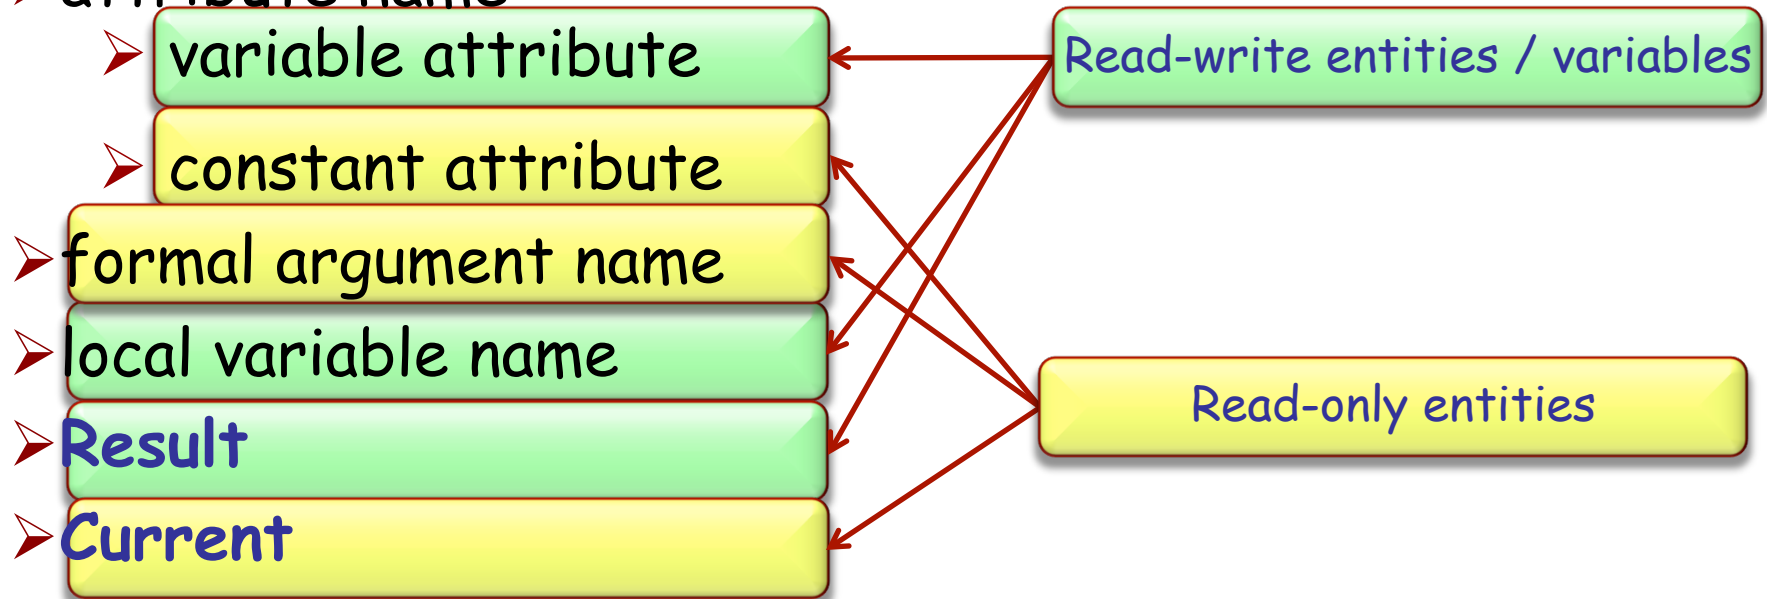

➤ local variable name

➤ **Result**

➤ **Current**

Read-write entities / variables

Read-only entities

Only a **variable** can be used in a creation instruction and in the left part of an assignment

# Find 5 errors

Hands-On

```
class VECTOR
feature
  x, y: REAL

  copy_from (other: VECTOR)
  do
    Current := other
  end

  copy_to (other: VECTOR)
  do
    create other
    other.x := x
    other.y := y
  end

  reset
  do
    create Current
  end
end
```

Current is not a variable and can not be assigned to

other is a formal argument (not a variable) and thus can not be used in creation

other.x is a qualified attribute call (not a variable) and thus can not be assigned to

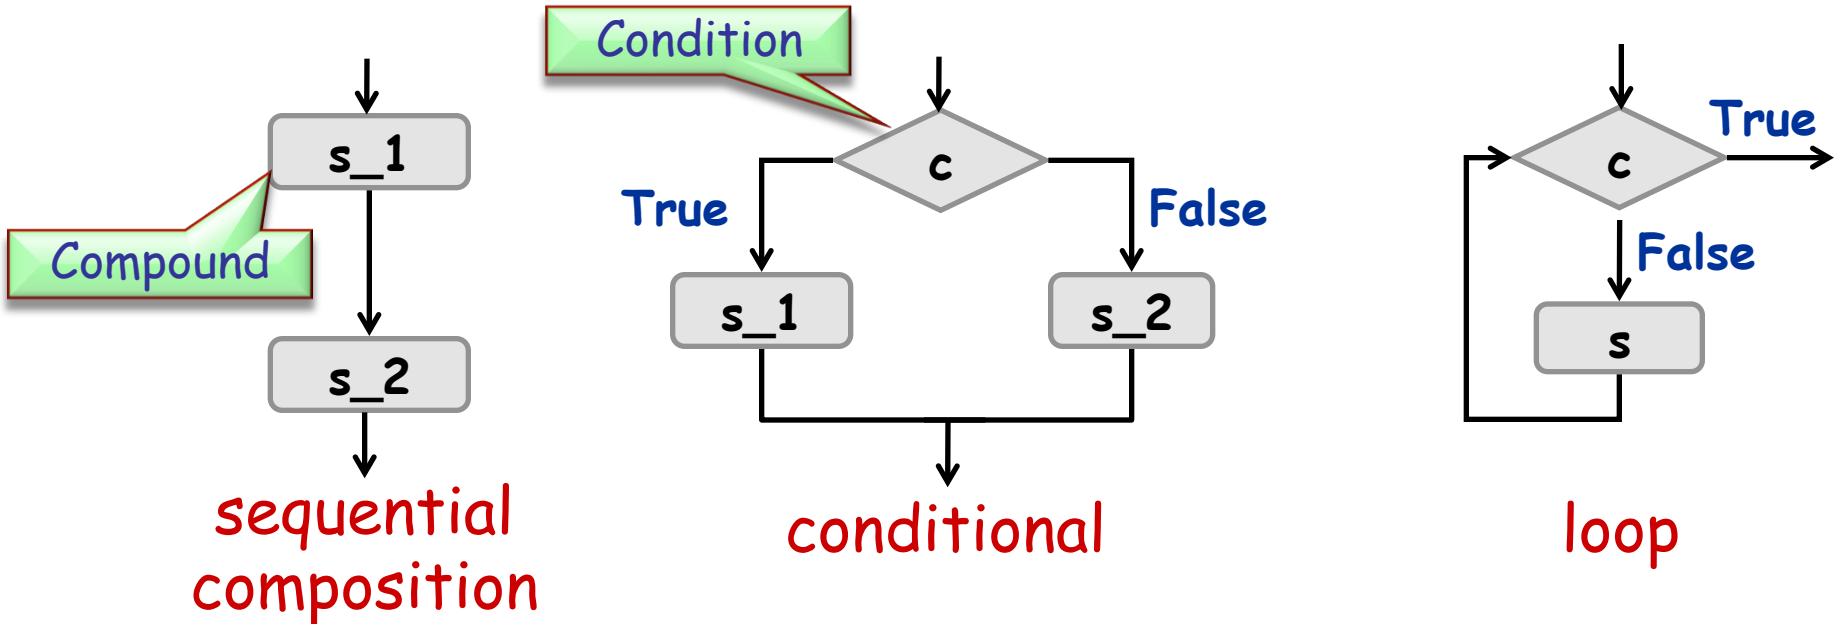

the same reason for other.y

Current is not a variable and thus can not be used in creation

# Structured programming

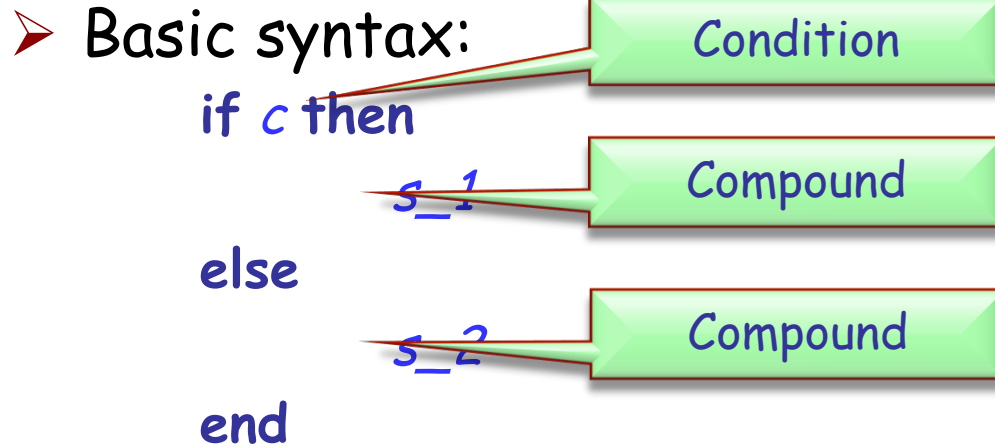

- In **structured programming** instructions can be combined only in three ways (constructs):

- Each of these blocks has a single entry and exit and is itself a (possibly empty) compound

# Conditional

➤ Could *c* be an integral expressions?

➤ No. *c* is a boolean expression (e.g., entity, query call of type **BOOLEAN**)

➤ Are these valid conditionals?

```
if c then  
  s_1  
end
```

Yes, **else** is optional

```
if c then  
end
```

Yes, *s\_1* could be empty.

```
if c then  
else  
end
```

Yes, *s\_1* and *s\_2* could be both empty.

# Calculating function's value

```
f(max: INTEGER; s: STRING): STRING
do
  if s.is_equal("Java") then
    Result := "J**a"
  else
    if s.count > max then
      Result := "<an unreadable German word>"
    end
  end
end
end
```

Calculate the value of:

- $f(3, \text{"Java"}) \rightarrow \text{"J**a"}$
- $f(20, \text{"Immatrikulationsbestätigung"}) \rightarrow \text{"<an unreadable German word>"}$
- $f(6, \text{"Eiffel"}) \rightarrow \text{Void}$

# Write a routine...

Hands-On

- ... that computes the maximum of two integers

```
max(a, b : INTEGER) : INTEGER
```

- ... that increases time by one second inside class *TIME*

```
class TIME  
  hour, minute, second : INTEGER  
  
  second_forth  
    do ... end  
  
  ...  
  
end
```

# Comb-like conditional

If there are more than two alternatives, you can use the syntax:

```
if c_1 then
  s_1
elseif c_2 then
  s_2
...
elseif c_n then
  s_n
else
  s_e
end
```

Condition

Compound

One word!

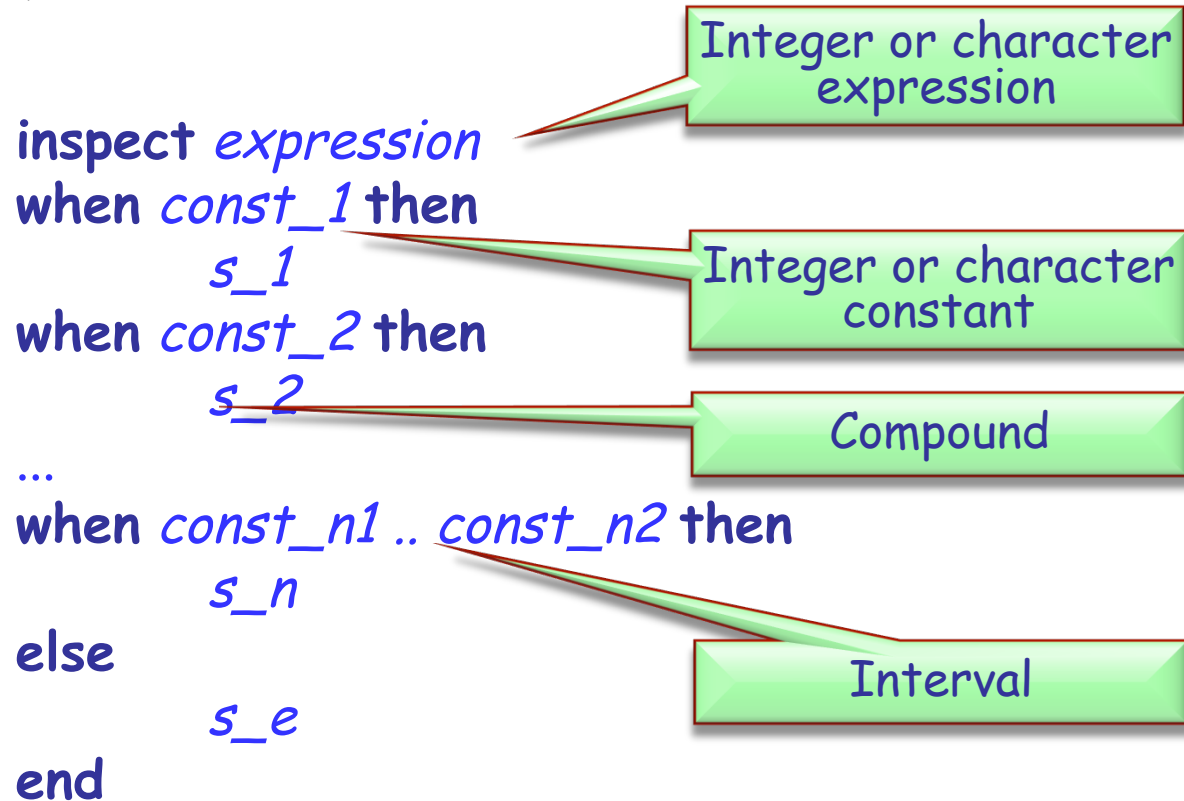

instead of:

```
if c_1 then
  s_1
else
  if c_2 then
    s_2
  else
    ...
    if c_n then
      s_n
    else
      s_e
    end
  end
  ...
end
end
```

# Multiple choice

If all the conditions have a specific structure, you can use the syntax:

# Lost in conditions

Hands-On

Rewrite the following multiple choice:

- using a comb-like conditional
- using nested conditionals

```
inspect user_choice
when 0 then
  print ("Hamburger")
when 1 then
  print ("Coke")
else
  print ("Not on the menu!")
end
```

```
if user_choice = 0 then
  print ("Hamburger")
elseif user_choice = 1 then
  print ("Coke")
else
  print ("Not on the menu!")
end
```

```
if user_choice = 0 then
  print ("Hamburger")
else
  if user_choice = 1 then
    print ("Coke")
  else
    print ("Not on the menu!")
  end
end
```

# Loop: Basic form

Syntax:

**from**

*initialization*

Compound

**until**

*exit\_condition*

Boolean expression

**loop**

*body*

Compound

**end**

# Compilation error? Runtime error?

Hands-On

```
f(x, y: INTEGER): INTEGER
```

```
do
  from
  until (x // y)
  loop
    "Print me!"
  end
end
```

Compilation error:  
integer expression  
instead of boolean

Compilation error:  
expression instead  
of instruction

```
f
```

```
do
  from
  until False
  loop
  end
end
```

Correct, but  
non-terminating

```
f(x, y: INTEGER): INTEGER
```

```
local
  i: INTEGER
do
  from i := 1 until (True)
  loop
    i := i * x * y
  end
end
```

Correct

# Simple loop

Hands-On

How many times will the body of the following loop be executed?

*i* : INTEGER

from

*i* := 1

In Eiffel we usually start counting from 1

until

*i* > 10

10

loop

*print* ("I will not say bad things about assistants")

*i* := *i* + 1

end

from

*i* := 10

∞

until

*i* < 1

Caution! Loops can be infinite!

loop

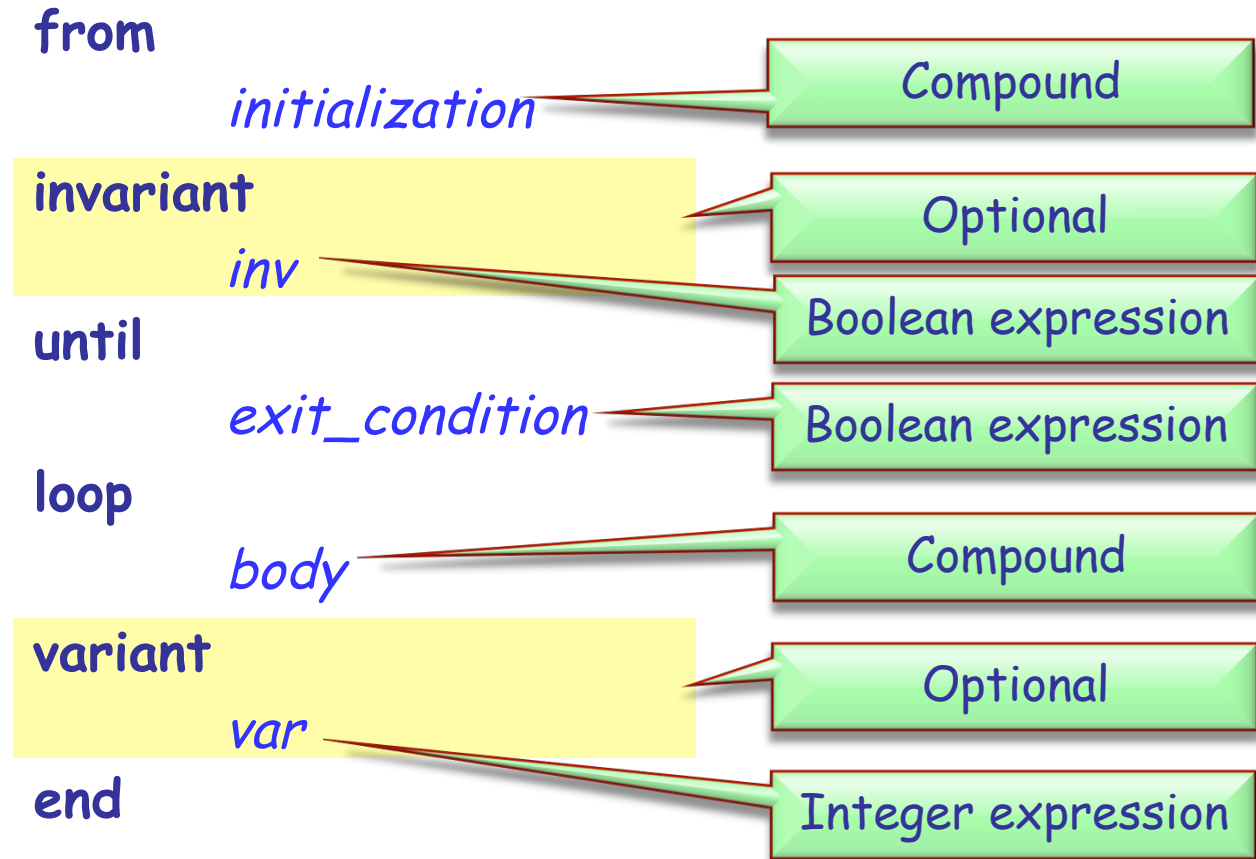

*print* ("I will not say bad things about assistants")

end

# Loop: More general form

Syntax:

**Loop invariant** (do not confuse with class invariant)

- holds before and after the execution of **loop** body
- captures how the loop iteratively solves the problem: e.g. “to calculate the sum of all  $n$  elements in a list, on each iteration  $i$  ( $i = 1..n$ ) the sum of first  $i$  elements is obtained”

**Loop variant**

- integer expression that is *nonnegative* after execution of **from** clause and after each execution of **loop** clause and strictly *decreases* with *each iteration*
- a loop with a correct variant can not be infinite (why?)

# Example – sum of the first n integers

*sum* (*n*: INTEGER): INTEGER

-- Compute the sum of the numbers from 0 to `n`

require

$0 \leq n$

do

from

Result := 0

$i := 1$

invariant

$1 \leq i$  and  $i \leq n+1$

Result =  $(i * (i - 1)) // 2$

until

$i > n$

loop

Result := Result +  $i$

$i := i + 1$

variant

$n - i + 1$

end

ensure

Result =  $(n * (n + 1)) // 2$

end

What are the loop invariants and variants here?

# What does this function do?

Hands-On

```
factorial (n : INTEGER) : INTEGER
  require
    n >= 0
  local
    i : INTEGER
  do
    from
      i := 2
      Result := 1
    until
      i > n
    loop
      Result := Result * i
      i := i + 1
    end
  end
end
```

# Invariant and variant

Hands-On

What are the invariant and variant of the “factorial” loop?

```
from
    i := 2
    Result := 1
invariant
    Result = factorial(i - 1)
until
    i > n
loop
    Result := Result * i
    i := i + 1
variant
    n - i + 2
end
```

Result = 6 = 3!

# Writing loops

Hands-On

Implement a function that calculates Fibonacci numbers, using a loop

```
fibonacci (n : INTEGER) : INTEGER
    -- n-th Fibonacci number
    require
        n_non_negative : n >= 0
    ensure
        first_is_zero : n = 0 implies Result = 0
        second_is_one : n = 1 implies Result = 1
        other_correct : n > 1 implies Result = fibonacci (n - 1) +
fibonacci (n - 2)
    end
```

# Writing loops (solution)

Hands-On

```
fibonacci(n: INTEGER) : INTEGER
  local
    a, b, i: INTEGER
  do
    if n <= 1 then
      Result := n
    else
      from
        a := 0
        b := 1
        i := 1
      invariant
        a = fibonacci(i - 1)
        b = fibonacci(i)
      until
        i = n
      loop
        Result := a + b
        a := b
        b := Result
        i := i + 1
      variant
        n - i
    end
  end
end
```

- Attributes, formal arguments, and local variables
  - Scope
- Control structures
